Note that the filter output lies in the past, namely at T_valid_start

Test scenario 1:

Test scenario 2:

Perform convolve every incoming block, ring buffer is 3x BLOCK_SIZE block Maximized N_taps given BLOCK_SIZE and N_blocks			c: #0: start-up				#1: start-up					#2						#3						#4

Optimal scenario:

Perform convolve every incoming block, maximize N_taps given BLOCK_SIZE and N_blocks

Fs BLOCK_SIZE N_blocks	20000 Hz 2000 samples 21 int						
rb_capacity	42000 samples	= BLOCK_SIZE * N_blocks					
N_taps	40001 samples	= BLOCK_SIZE * (N_blocks - 1) + 1 == max that fits using rb_capacity					
Fred Harris' approximatio	n	Multirate Signal Processing for Communication Systems, Fredric J. Harris, 2004, page 216, equation (8.16)					
f_pass	49 Hz						
f_stop	50 Hz						
filter attenuation	44.00 dB	= N_taps * 22 * ((f_stop - f_pass) / Fs)					
N_sig_into_conv	42000 samples	= BLOCK_SIZE + N_taps - 1 == rb_capacity by optimal design					
offset_sig_into_conv	0 samples	= rb_capacity - N_sig_into_conv == 0 by optimal design					
N_conv_valid_out	2000 samples	= rb_capacity - N_taps + 1 == BLOCK_SIZE by optimal design					
offset_conv_valid_out	20000 samples	= INT((N_taps - 1) / 2)					
idx_rb_valid_start	20000 samples	= offset_conv_valid_out + offset_sig_into_conv == offset_conv_valid_out by optimal design					
T_valid_start	1.00 s	= idx_rb_valid_start / Fs i.e. Starting index within the input-signal ring buffer aligning to the time stamps of the computed valid filter output					
T_settle_filter	2.00 s	= (N_blocks - 1) * BLOCK_SIZE / Fs i.e. Wallclock time when the filter starts outputting when being fed with incoming realtime data. Here, the term `settle` is not to be confused with the filter theoretical response time to an impulse.
